Review: Virtual Memory & Physical Memory

 A page table contains page table entries (PTEs) that map virtual pages to physical pages.

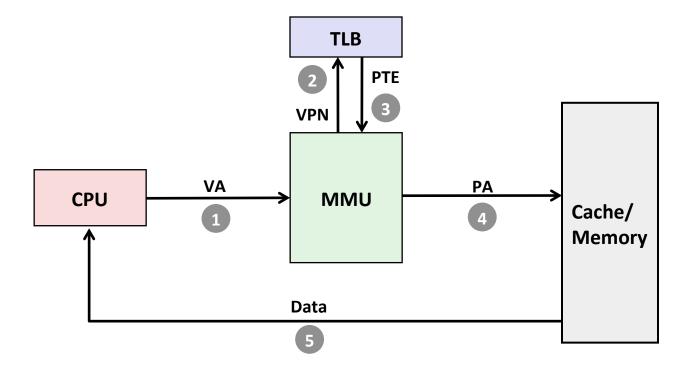

Review: Translating with a k-level Page Table

Having multiple levels greatly reduces page table size

Review: Translation Lookaside Buffer (TLB)

A small cache of page table entries with fast access by MMU

Typically, a TLB hit eliminates the k memory accesses required to do a page table lookup.

Review: Set-Assoc. Cache: Read Locate set Check if any line in set has matching tag E = 2^e lines per set Yes + line valid: hit Locate data starting at offset Address of word: t bits s bits b bits $S = 2^s$ sets **CT** CO index offset tag data begins at this offset 0 **B-1** tag valid bit $B = 2^b$ bytes per cache block (the data)

Address of word:
t bits s bits

data begins at this offset

Review of Symbols

Basic Parameters

- N = 2ⁿ: Number of addresses in virtual address space
- M = 2^m: Number of addresses in physical address space
- **P = 2**^p : Page size (bytes)

Components of the virtual address (VA)

- **VPO**: Virtual page offset
- VPN: Virtual page number
- **TLBI**: TLB index
- TLBT: TLB tag

0 1 2

E = 2^e lines per set

S = 2^s sets

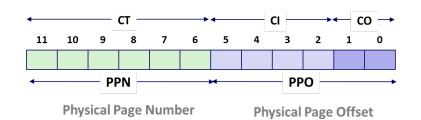

valid bit

Components of the physical address (PA)

- PPO: Physical page offset (same as VPO)
- PPN: Physical page number
- CO: Byte offset within cache line
- CI: Cache index
- CT: Cache tag

(bits per field for our simple example)

B = 2^b bytes per cache block (the data)

Today

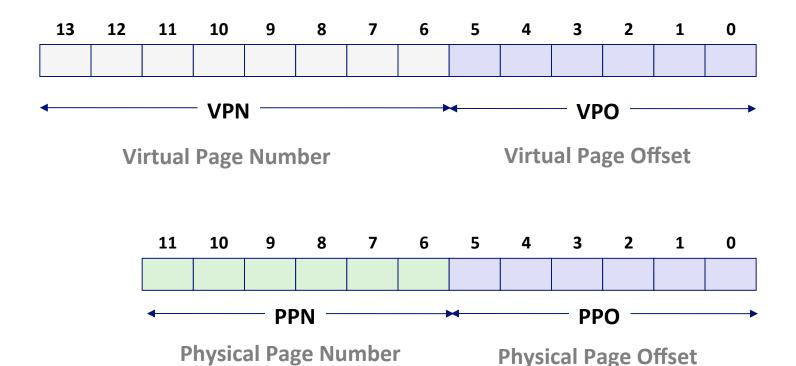

Textbook: [CS:APP3e] 9.6.4, 9.7, 9.8

- Simple memory system example
- Case study: Core i7/Linux memory system
- Memory mapping

Simple Memory System Example

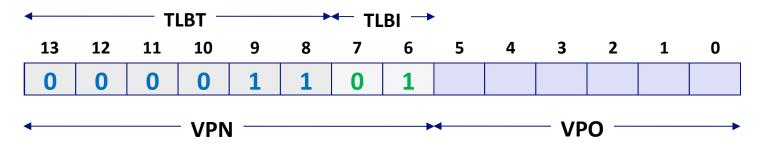

Addressing

- 14-bit virtual addresses
- 12-bit physical address
- Page size = 64 bytes

Simple Memory System TLB

- 16 entries
- 4-way associative

VPN = 0b1101 = 0x0D

Translation Lookaside Buffer (TLB)

Set	Tag	PPN	Valid									
0	03	-	0	09	0D	1	00	-	0	07	02	1
1	03	2D	1	02	1	0	04	-	0	0A	-	0

Intel Core i7 Memory System

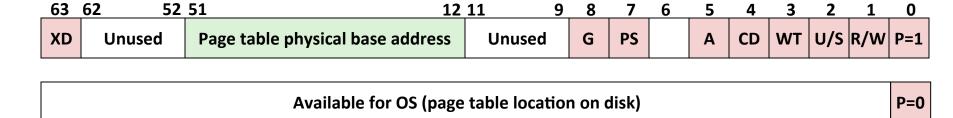

End-to-end Core i7 Address Translation

Core i7 Level 1-3 Page Table Entries

Each entry references a 4K child page table. Significant fields:

P: Child page table present in physical memory (1) or not (0).

R/W: Read-only or read-write access access permission for all reachable pages.

U/S: user or supervisor (kernel) mode access permission for all reachable pages.

WT: Write-through or write-back cache policy for the child page table.

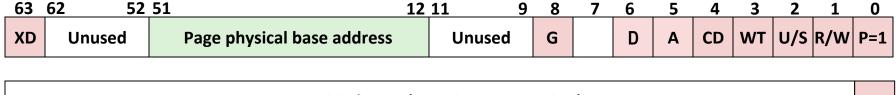

A: Reference bit (set by MMU on reads and writes, cleared by software).

PS: Page size either 4 KB or 4 MB (defined for Level 1 PTEs only).

Page table physical base address: 40 most significant bits of physical page table address (forces page tables to be 4KB aligned)

XD: Disable or enable instruction fetches from all pages reachable from this PTE.

Core i7 Level 4 Page Table Entries

Available for OS (page location on disk)

P=0

Each entry references a 4K child page. Significant fields:

P: Child page is present in memory (1) or not (0)

R/W: Read-only or read-write access permission for child page

U/S: User or supervisor mode access

WT: Write-through or write-back cache policy for this page

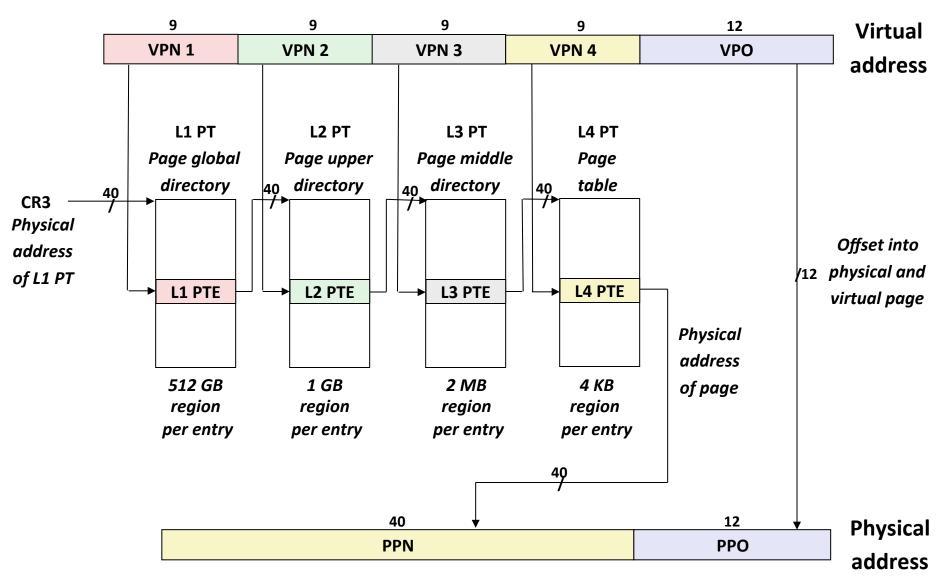

A: Reference bit (set by MMU on reads and writes, cleared by software)

D: Dirty bit (set by MMU on writes, cleared by software)

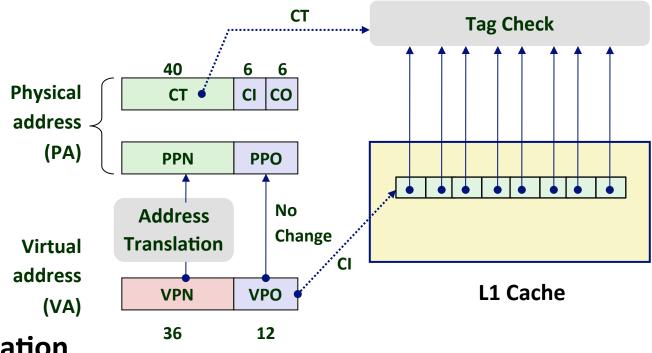

Page physical base address: 40 most significant bits of physical page address (forces pages to be 4KB aligned)

XD: Disable or enable instruction fetches from this page.

Core i7 Page Table Translation

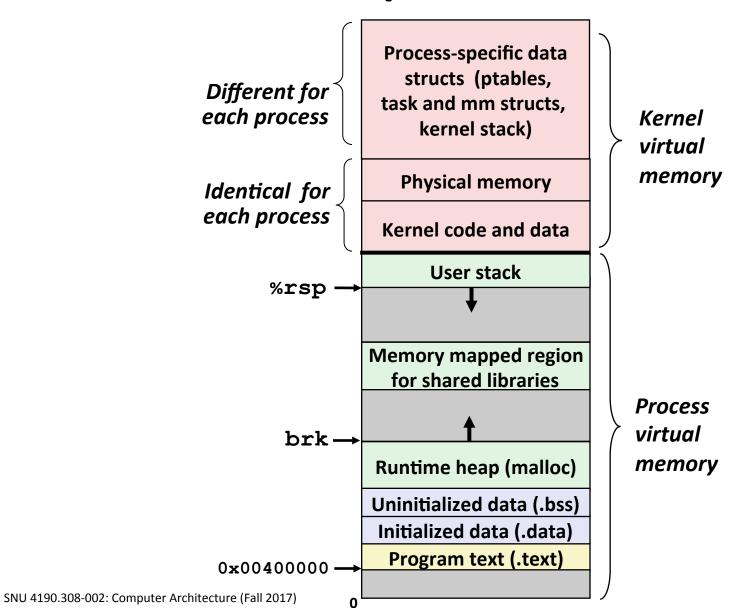

Cute Trick for Speeding Up L1 Access

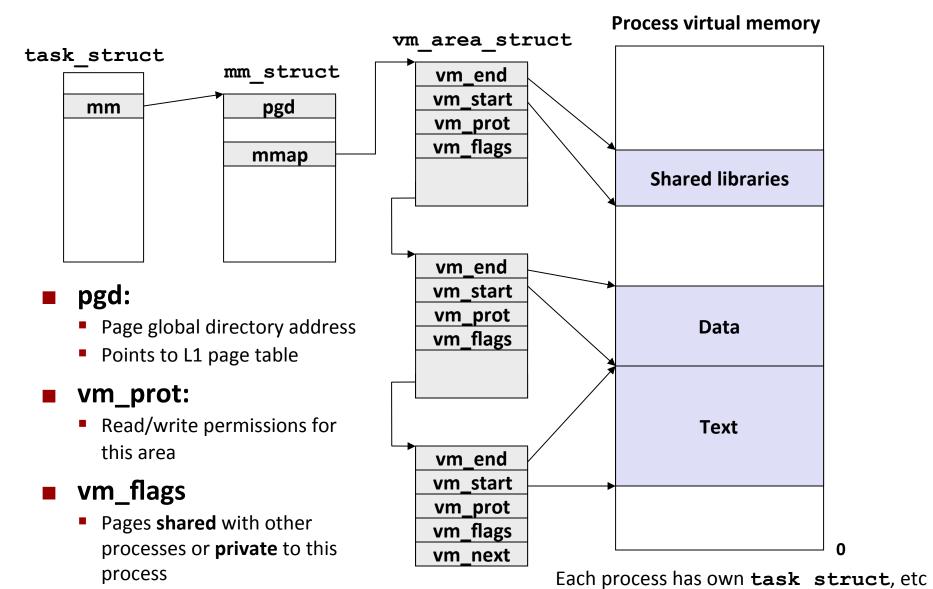

Observation

- Bits that determine CI identical in virtual and physical address
- Can index into cache while address translation taking place
- Generally we hit in TLB, so PPN bits (CT bits) available next
- "Virtually indexed, physically tagged"
- Cache carefully sized to make this possible

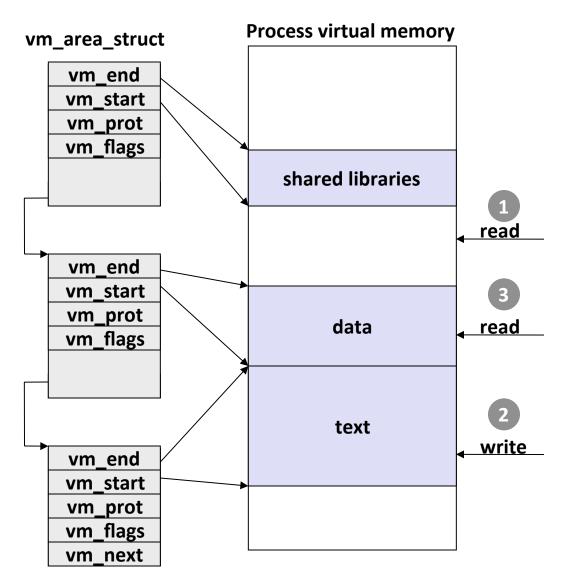

Virtual Address Space of a Linux Process

Linux Organizes VM as Collection of "Areas"

Linux Page Fault Handling

Segmentation fault: accessing a non-existing page

Normal page fault

Protection exception:

e.g., violating permission by writing to a read-only page (Linux reports as Segmentation fault)

Today

Textbook: [CS:APP3e] 9.6.4, 9.7, 9.8

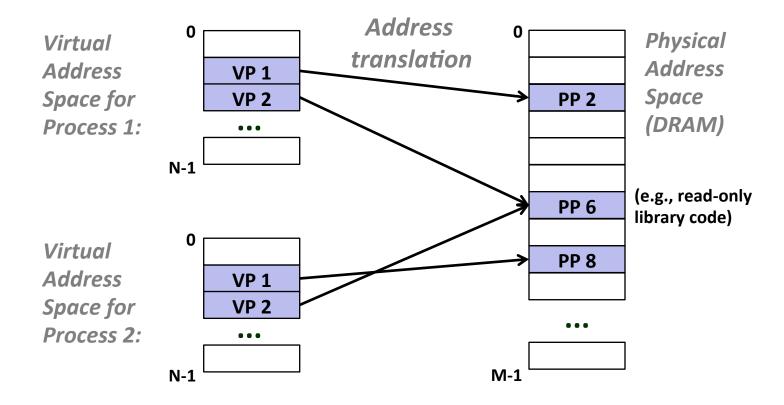

- Simple memory system example
- Case study: Core i7/Linux memory system
- Memory mapping

Memory Mapping

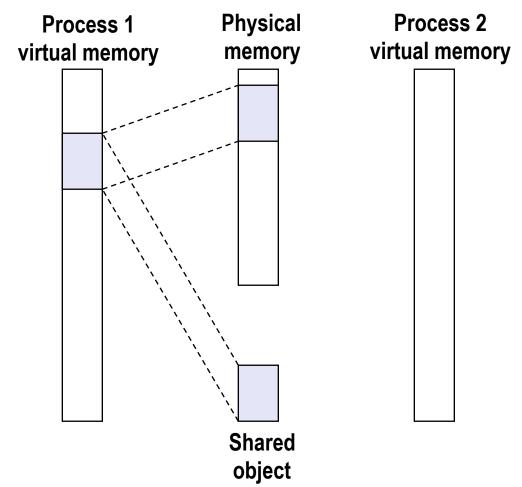

- VM areas initialized by associating them with disk objects.
 - Called memory mapping
- Area can be backed by (i.e., get its initial values from):
 - Regular file on disk (e.g., an executable object file)
 - Initial page bytes come from a section of a file
 - Anonymous file (e.g., nothing)
 - First fault will allocate a physical page full of 0's (demand-zero page)
 - Once the page is written to (dirtied), it is like any other page
- Dirty pages are copied back and forth between memory and a special swap file.

Review: Memory Management & Protection

Code and data can be isolated or shared among processes

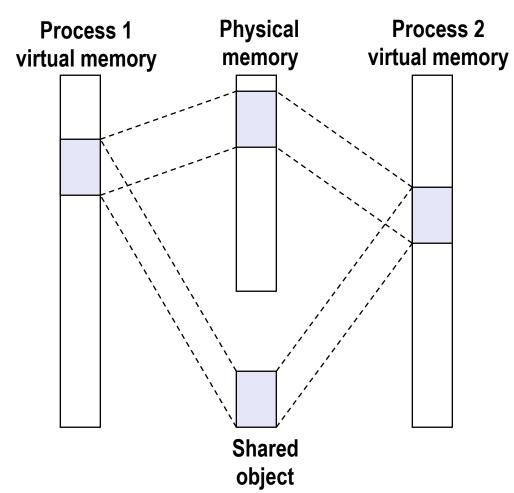

Sharing Revisited: Shared Objects

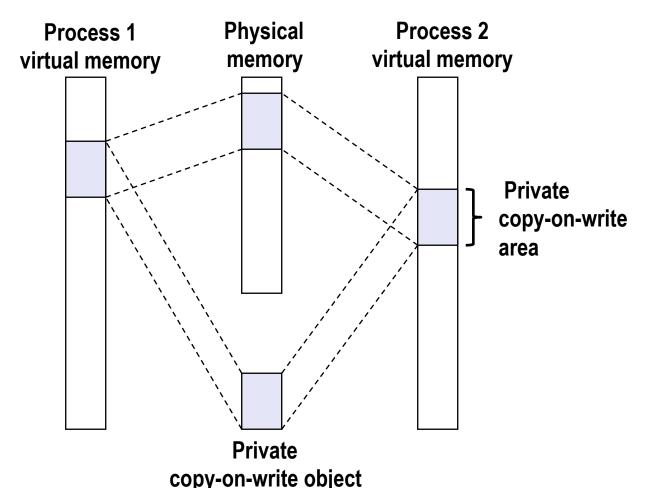

Process 1 maps the shared object (on disk).

Sharing Revisited: Shared Objects

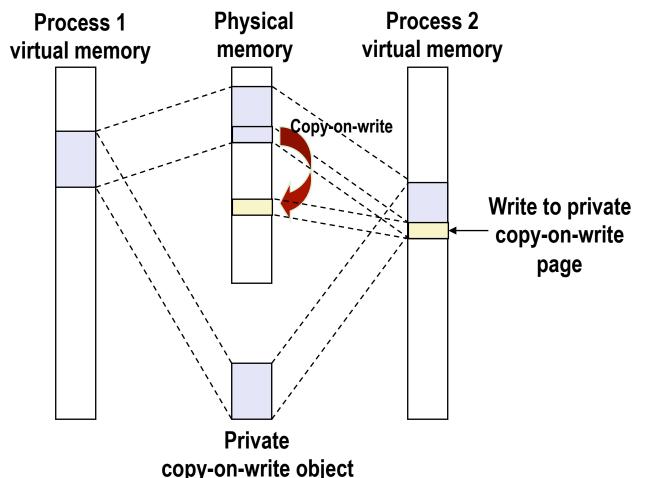

- Process 2 maps the same shared object.
- Notice how the virtual addresses can be different.

Sharing Revisited: Private Copy-on-write (COW) Objects

- Two processes mapping a private copy-on-write (COW) object
- Area flagged as private copy-onwrite
- PTEs in private areas are flagged as read-only

Sharing Revisited: Private Copy-on-write (COW) Objects

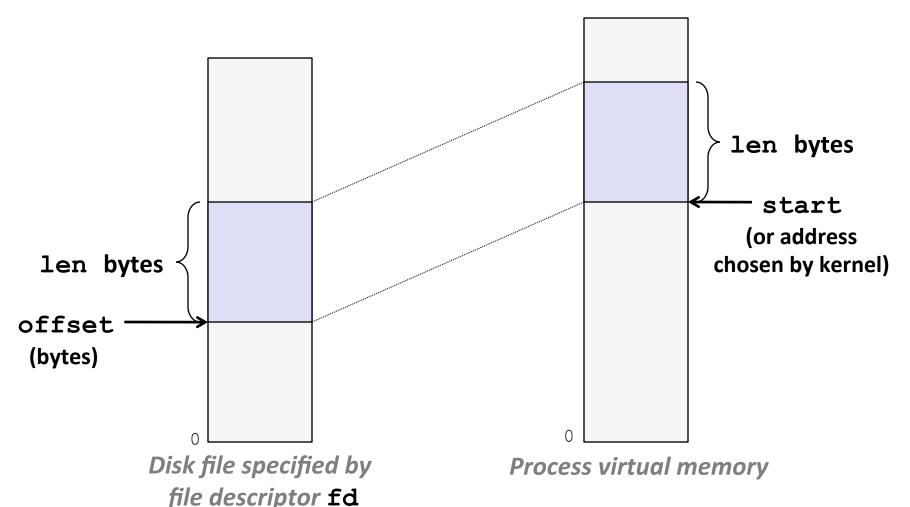

- Instruction writing to private page triggers protection fault.
- Handler creates new R/W page.
- Instruction restarts upon handler return.
- Copying deferred as long as possible!

User-Level Memory Mapping

- Map len bytes starting at offset offset of the file specified by file description fd, preferably at address start
 - start: may be 0 for "pick an address"
 - prot: PROT_READ, PROT_WRITE, PROT_EXEC, ...
 - flags: MAP_ANON, MAP_PRIVATE, MAP_SHARED, ...
- Return a pointer to start of mapped area (may not be start)

User-Level Memory Mapping

Example: Using mmap to Copy Files

■ Copying a file to stdout without transferring data to user space

```
#include "csapp.h"
void mmapcopy(int fd, int size)
    /* Ptr to memory mapped area */
    char *bufp;
    bufp = mmap(NULL, size,
                PROT READ,
                MAP PRIVATE,
                fd, 0);
    write(1, bufp, size);
    return;
                        mmapcopy.c
```

```
/* mmapcopy driver */
int main(int argc, char **argv)
{
    struct stat stat:
    int fd:
    /* Check for required cmd line arg */
    if (argc != 2) {
        printf("usage: %s <filename>\n",
               argv[0]);
        exit(0);
    /* Copy input file to stdout */
    fd = open(argv[1], 0_RDONLY, 0);
    fstat(fd, &stat);
    mmapcopy(fd, stat.st_size);
    exit(0);
                              mmapcopy.c
```
